

Antigravity / RAIG App Summary

One-page repo-based summary generated from README, source code, package manifests, and compose files.

What It Is

Antigravity is a multi-service algorithmic trading app with a **Next.js dashboard**, a **Go trading engine**, and an **optional Node browser bridge**.

Repo evidence shows desks for crypto, NIFTY options and stocks, MCX commodities, forex, and trade-history monitoring.

Who It's For

Primary persona (inferred from repo evidence): a trading operator or quant-minded user who wants to monitor strategies, inspect signals, and control paper or broker-connected trading desks from one UI.

Formal persona document: Not found in repo.

What It Does

- Multi-workspace dashboard for crypto, NIFTY options, NIFTY option selling, NIFTY stocks, MCX, forex, and trade history.
- Live positions, strategies, trade stats, activity feed, and in-memory engine log viewing.
- Paper-trading flows plus replay/backtest-oriented panels for workspace review.
- Option-chain, candle, stream, quote, and probe routes for BTC and NIFTY market views.
- Admin controls for kill switch, close-all, reset, and clear-history actions.
- AI insights, pending-signal review, audit logs, and optional ChatGPT browser bridge workflow.
- Angel One routes for funds, orders, cancel-order, and broker order placement.

How It Works

- **UI + app server:** Next.js 16 / React 19 app in *client/*; pages load *TradingDashboard*, and hooks fetch Go APIs or local Next API routes.
- **Core engine:** Go service in *engine/cmd/antigravity* wires market data, strategies, risk, positions, execution, persistence, admin controls, and Prometheus metrics on port 8080.
- **Data + infra:** Postgres/TimescaleDB, Redis, Prometheus, and Grafana are defined in repo compose files; the client also persists NIFTY state through */api/nifty/state* into Postgres.
- **Optional AI bridge:** *bridge/bridge.js* polls */api/ai/pending*, automates ChatGPT in Chrome via Puppeteer, then posts verdicts back to */api/ai/bridge-result*.

How To Run

1. Copy **.env.example** to **.env** and fill the required API, broker, and DB values.
2. Start infrastructure from **infrastructure/** with **docker-compose up -d**.
3. Start the dashboard from **client/** with **npm install** and **npm run dev**, then open **http://localhost:3000**.
4. Start the engine from **engine/** with **go run cmd/antigravity/main.go**.
5. Optional bridge: from **bridge/**, run **node bridge.js** after launching Chrome with remote debugging. Bridge steps are documented in **bridge/README.md**.
